

only because it effects an acceleration of the rate of the second section. This gives the first approximation to the correlation between the sections of the process. Just as the standard of living is the consumer to the first section, so the ~~same~~ first section is consumer to the second, and the second is consumer to the third. But while the standard of living is for its own sake, and the activity of the first section is for the standard of living and a rate that, roughly, is equivalent to its rate, the activity of the second section is for the acceleration of the first, the the activity of the third section is for the acceleration of the second, and so on in so far as there are higher sections to the process.
